It has been 15 years since the first report on the isolation of anti-Gal from human serum and the demonstration that this antibody is the most prevalent antibody in humans (Galili et al. , J. Exp. Med. 160: 1519, 1984). Subsequent interdisciplinary studies in immunology, carbohydrate biochemistry, molecular biology, and evolution demonstrated the highly restricted specificity of anti-Gal for the carbohydrate epitope Gal α 1-3Gal β 1-4GlcNAc-R, (termed here the α -gal epitope), the unprecedented evolutionary pattern of distribution of α -gal and anti-Gal in mammals, and explained the evolution of this antigen and antibody by analysis of the α 1,3galactosyltransferase gene, the gene that encodes the enzyme that synthesizes the α -gal epitope. These studies have suggested that a major selection process that occurred in the course of evolution of ancestral Old World primates resulted in the inactivation of the α 1,3galactosyltransferase gene and the subsequent appearance of anti-Gal in these primates. Other studies in immunoparasitology have demonstrated the possible physiologic significance of anti-Gal in protection against certain parasitic infections. Major scientific attention was focused on α -gal and anti-Gal with the realization in the early nineties that the interaction between this antigen and antibody is the major obstacle to xenotransplantation. The success of immunosuppressive drugs, in the last two decades of the 20th century, in preventing allograft rejection, has raised hopes for cure in many patients in need of organ transplant. Because of limited supply of allografts, only 20 of patients receive the needed organ.
